Guidelines for the Mongolian Food Composition

Sample booklet

About this booklet

This is a short sample booklet added so that the Books page of the Mongolian Food Composition Database has a document to open. Replace it with the official publication when it is available.

What is a food composition table?

A food composition table lists the amount of nutrients in foods, usually per 100 g of the edible part. The main groups are proximates (energy, water, protein, fat, ash, carbohydrate), minerals (for example calcium, iron, phosphorus, potassium, sodium) and vitamins (for example vitamin A, thiamin, riboflavin, vitamin C).

Calculating energy

Energy can be estimated from the macronutrients with the standard factors: Energy (kcal) = Protein x 4 + Fat x 9 + Carbohydrate x 4, where each amount is in grams. The Calculation page of this site uses the same idea and scales values to the amount of food you enter.

Using the database

Use the Search page to find a food by name or by food group, and choose which tables to show: nutrients, collection information, edible and inedible parts, processing conditions, description and images. The Overview page shows a map; selecting a province lists the foods collected there.

Good practice

Always check the food name, the part analysed and the way the sample was prepared before using a value. Values for raw and cooked forms of the same food can differ a lot.
